

Social Media Brand Analytics

Netflix vs Amazon Prime Video on BlueSky

Public social media text analytics, sentiment analysis, topic modelling and micro-influencer screening

4,000 Raw posts collected	3,532 Clean brand posts	1,743 English text posts	2 Brands compared	2 Recommended pilot creators
------------------------------	----------------------------	-----------------------------	----------------------	---------------------------------

Executive summary

This case study analyses public BlueSky discussion around Netflix and Amazon Prime Video. The objective is to compare brand visibility, audience engagement, sentiment, commercial conversation themes, and potential micro-influencer opportunities using a reproducible Python-based social media analytics workflow. The analysis is based on a snapshot of 4,000 raw posts, reduced after deduplication and cleaning to 1,888 Netflix posts and 1,644 Amazon Prime Video posts. Sentiment and text modelling were conducted on an English-language subset of 1,106 Netflix posts and 637 Amazon Prime Video posts.

- Netflix generated greater conversation volume, more unique users and broader hashtag diversity, indicating stronger visibility in general entertainment discussion.
- Amazon Prime Video generated stronger audience response, with higher average engagement per post and a stronger positive sentiment balance in the English-language subset.
- Theme analysis positioned Netflix as a broad entertainment conversation brand, while Amazon Prime Video appeared more strongly associated with content access, platform availability and event-style viewing.
- The recommended pilot micro-influencer candidates were gociety.bsky.social for Amazon Prime Video and thebearupthere.bsky.social for Netflix, selected using engagement quality and account-suitability criteria.

1. Project context and business question

Streaming platforms compete not only through subscription offers and content libraries, but also through how audiences discuss, recommend and react to brands online. This project frames social media data as a brand intelligence source. The core business question is:

Which brand shows stronger audience momentum on BlueSky, and where can each brand improve its social engagement strategy?

The work is intended as an exploratory snapshot rather than a full market measurement system. It demonstrates how public post-level data can be transformed into commercial signals for marketing, brand tracking and creator partnership decisions.

2. Data and analytical workflow

Posts were collected through keyword-based search. Netflix queries included terms such as 'netflix' and '#netflix'. Amazon Prime Video queries included 'prime video' and 'amazon prime video'. The resulting workflow moved from raw post collection to cleaned brand-level datasets, English-language text analysis, theme extraction and micro-influencer screening.

Dataset stage	Netflix	Amazon Prime Video	Total
Raw posts collected	2,000	2,000	4,000
Clean brand-analysis posts	1,888	1,644	3,532
English-language text posts	1,106	637	1,743

Table 1. Cleaned analysis datasets

A combined engagement score was calculated by summing likes, reposts, replies and quote posts. For text analytics, posts were cleaned and transformed using TF-IDF before non-negative matrix factorisation (NMF) was used to identify interpretable themes. Sentiment was estimated using VADER, which is suitable for short social media text but should still be interpreted as a directional signal rather than a perfect reading of intent.

3. Brand visibility and engagement

Figure 1. Brand visibility in the cleaned dataset

Netflix led on visibility. It appeared in more cleaned posts and was associated with more unique users, suggesting wider general discussion in the collected BlueSky snapshot. However, brand visibility alone did not translate into stronger audience amplification.

Figure 2. Engagement intensity by brand

Amazon Prime Video generated a stronger engagement profile, with average engagement of 9.18 per post compared with 2.28 for Netflix. Its total engagement was also higher despite fewer posts. This indicates that Amazon Prime Video's posts in the sample were more likely to trigger visible user interaction.

4. Sentiment and theme analysis

Sentiment analysis was conducted on the English-language text subset. Both brands had more positive than negative posts, but Amazon Prime Video had the stronger sentiment balance.

Figure 3. Sentiment distribution by brand

Brand	Positive	Neutral	Negative	Net sentiment
Amazon Prime Video	58.87%	21.66%	19.47%	39.40%
Netflix	43.85%	32.91%	23.24%	20.61%

Table 2. Sentiment summary for English-language posts

Figure 4. Refined commercial theme comparison

The theme analysis shows different brand positions. Netflix was more strongly associated with viewer opinion and recommendation, reflecting audience-led conversation around shows and viewing choices. Amazon Prime Video was more

strongly associated with platform availability, access and live sport or event streaming. Both brands were strongly linked with releases and trailers, but the underlying conversation drivers differed.

5. Micro-influencer screening

Micro-influencer candidates were not selected only on total engagement. The screening approach balanced brand-related posting activity, total engagement, average and median engagement, maximum engagement, and account-type suitability. Likely media feeds, publisher-style accounts and invalid handles were treated cautiously to avoid recommending accounts that may not function as authentic micro-influencer partners.

Brand	Recommended handle	Posts	Total eng.	Avg eng.	Median eng.	Score
Amazon Prime Video	gociety.bsky.social	4	250	62.5	58.0	0.97
Netflix	thebearupthere.bsky.social	2	203	101.5	101.5	0.96

Table 3. Recommended pilot micro-influencer candidates

Figure 5. Average engagement for recommended accounts

6. Commercial interpretation and recommendations

The findings point to two different strategic priorities.

- Netflix should focus on converting broad visibility into stronger advocacy. It can do this through fan-led campaigns, recommendation prompts, community discussion around major releases, and creative assets that encourage positive reactions rather than passive mentions.
- Amazon Prime Video should scale its stronger audience response. It should build campaigns around high-engagement moments such as franchise releases, live sport, event viewing and platform-access messaging.
- Both brands should test micro-influencer pilots using controlled objectives: engagement quality, sentiment shift, topic relevance and post-level reach. Pilot performance should be compared against baseline organic discussion.

7. Limitations and next steps

- The analysis is a snapshot of BlueSky conversation, not a full market-wide brand tracking system.
- No geographic filter was applied, so findings should not be interpreted as UK-specific or region-specific.

- Automated sentiment can misread sarcasm, humour, cultural references and short-form ambiguity.
- Follower and network data were unavailable, so micro-influencer suitability was inferred from post-level behaviour rather than full audience quality.
- A stronger future version would collect over a longer period and compare results around major release, pricing and live-event windows.

This demonstrates Python data collection, text preprocessing, sentiment analysis, TF-IDF/NMF topic modelling, engagement analysis and business recommendation development.
